(Received 15 October 2012; revised manuscript received 29 April 2013; published 27 September 2013)

We study a phase oscillator network on a circle with an infinite-range interaction. First, we treat the Mexican-hat interaction with the zeroth and first Fourier components. We give detailed derivations of the auxiliary equations for the phases and self-consistent equations for the amplitudes. We solve these equations and characterize the nontrivial solutions in terms of order parameters and the rotation number. Furthermore, we derive the boundaries of the bistable regions and study the bifurcation structures in detail. Expressions for location-dependent resultant frequencies and entrained phases are also derived. Secondly, we treat a different interaction that is composed of mth and rth Fourier components, where m < n, and we study its nontrivial solutions. In both cases, the results of numerical simulations agree quite well with the theoretical results.

I. INTRODUCTION

Synchronization phenomena are ubiquitous in nature, and they are very important to living organisms. Typical examples include the simultaneous emission of light by fireflies, the rhythm of the heart composed of a population of cardiac muscle cells, and circadian rhythms [1,2].

Pioneering studies on such behavior were done by Winfree [3] and Kuramoto [4]. In particular, Kuramoto regarded synchronization as a phase transition and devised a model in which synchronization occurs as a phase transition in a nonequilibrium system. In general, when nonlinear dynamical systems with stable limit cycle oscillators are weakly coupled, the whole system can be described in terms of the phases of the oscillators, and the dynamical equation reduces to the evolution equation for phases [4]. Kuramoto proposed the so-called Kuramoto model, which is a coupled phase oscillator network. He found that the synchronization-desynchronization phase transition takes place when the system parameter reaches a certain value, and he derived an analytic expression for the critical point [5]. Since Kuramoto’s analysis of globally coupled oscillators, oscillator networks with both short-range and intermediate-range interactions have been studied [6]. Oscillators with global and random interactions [7] and with sparse and random interactions [8] have also been studied. Moreover, a number of studies have analyzed the stability of the stationary states [9–11]. Many of these studies use the Fokker-Planck equation to derive a phase distribution density function with or without external noise. In particular, Otto and Antonsen derived evolution equations for the order parameters by assuming a special form for the Fourier components of the phase distribution density function [12]. Since this study, many studies have been published on the dynamical behavior of order parameters [13,14]. One of the interesting findings is the so-called Chimera state, in which some fraction of the oscillators are perfectly synchronized while the remainder are desynchronized [15–17]. Another topic on general coupled oscillator networks is noise-induced synchronization. It has been found that two identical nonlinear oscillators synchronize in the presence of common external Gaussian noise [18]. The findings of this study have been extended to include systems with common and oscillator-dependent noise [19,20], noise in the form of random impulses [21], and common noise consisting of only two values [22]. A review of the Kuramoto model and its extensions is available elsewhere [23]. There have also been extensive studies on the statistical and dynamical properties of the mean-field XY model (HMF XY model) of conservative dynamical systems that are related to oscillator network models of dissipative dynamical systems [24,25].

In our previous study [26], we investigated global coupled phase oscillators arranged on a circle. The interaction between two elements depended on their distance. In particular, we studied the Mexican-hat interaction, which is used in neuroscience studies to model feature extraction cells in the visual cortex and embodies the property that a firing cell excites nearby cells and inhibits distant cells [27]. The interaction is composed of the zeroth and first Fourier components. We proposed a method to derive auxiliary equations that enable us to determine the phases of three complex order parameters completely. By using these phases, we obtained expressions for the self-consistent equations (SCEs) of the amplitude of the order parameters and equations for the boundaries of the bistable regions. We performed numerical simulations and found that they agreed quite well with the theoretical results.

In this study, first we treat the interaction with the zeroth and first Fourier components. We call the Mexican-hat interaction model 1. This model was studied previously. In this paper, we give a derivation of the auxiliary equations for the phases and self-consistent equations for the amplitudes, solve these equations, and derive the boundaries of the bistable regions. We obtain three nontrivial solutions that are characterized by the order parameters and the rotation numbers of the synchronized oscillators. We draw the phase diagram by using formulas for the phase boundaries derived using the unstable pendulum (Pn) solution. We find that the disappearance of coexistent regions between the U and S solutions and between the
\( Pn \) and \( S \) solutions is due to the unstable solution and the stable solution annihilating each other. This type of transition does not exist in the Kuramoto model. We also analytically derive the location-dependent distribution of the resultant frequencies and entrained phases and validate the theoretical results by simulation, except for the chaotic behavior of the desynchronized oscillators. Secondly, we treat a different interaction with the \( m \)th and \( n \)th Fourier components, where \( m < n \). We call this interaction model 2 and show theoretical and numerical results for it. For model 1, we solve the auxiliary equations. In Appendix B, we study model 1 and solve the auxiliary equations and SCEs for the case of \( m = 1 \) and \( n = 2 \), and we confirmed the theoretical results.

The structure of this paper is as follows. From Secs. II–VI, we study model 1. In Sec. II, we formulate the problem and describe the SCEs and auxiliary equations. The solutions of the auxiliary equations are also given. In Sec. III, we characterize the nontrivial solutions by introducing the rotation number. In Sec. IV, we give the SCEs for the nontrivial solutions. The phase diagram and bifurcation structure are studied in Sec. V. In Sec. VI, we show the results of numerical simulations and compare them with the theoretical results. In Sec. VII, we study model 2 and show theoretical and numerical results for it. Section VIII contains a summary and discussion of the results. In Appendix A, we derive the auxiliary equations and SCEs for model 1 and solve the auxiliary equations. In Appendix B, we derive the SCEs and relevant quantities for each phase. In Appendix C, we derive the condition for the existence of the \( Pn \) solution. The expressions for the phase boundaries are derived in Appendix D. Appendix E derives the SCEs for the spinning and pendulum solutions for model 2.

II. FORMULATION

Let us consider \( N \) equally spaced phase oscillators lying on a circle. We introduce the coordinate \( \theta \) on the circle, which takes values \( 0, \frac{2\pi}{N}, \frac{4\pi}{N}, \ldots, \frac{2(N-1)\pi}{N} \). Let \( \phi_0 \) be the phase of the oscillator at the coordinate \( \theta \), and assume that it obeys the following differential equation:

\[
\frac{d}{dt} \phi_0 = \omega_0 + \sum_{\theta'} J_{\theta, \theta'} \sin(\phi_{\theta'} - \phi_0). \tag{1}
\]

Here, \( \omega_0 \) is the natural frequency, and it is drawn from a probability density \( g(\omega) \). \( g(\omega) \) is assumed to be one-humped at \( \omega = \omega_0 \) and symmetric with respect to \( \omega_0 \). The interaction \( J_{\theta, \theta'} \) between oscillators at \( \theta \) and \( \theta' \) is assumed to be

\[
J_{\theta, \theta'} = \frac{J_0}{N} + \frac{J_1}{N} \cos(\theta - \theta'). \tag{2}
\]

This interaction has the properties of the Mexican-hat interaction described above. Now, let us introduce three complex order parameters,

\[
W = Re^{i\theta_0} = \frac{1}{N} \sum_{\theta} e^{i\phi_0}, \tag{3}
\]

\[
W_c = R_c e^{i\theta_0} = \frac{1}{N} \sum_{\theta} \cos \theta e^{i\phi_0}, \tag{4}
\]

\[
W_s = R_s e^{i\theta_0} = \frac{1}{N} \sum_{\theta} \sin \theta e^{i\phi_0}. \tag{5}
\]

By using these quantities, the evolution equation (1) can be rewritten as

\[
\frac{d}{dt} \phi_0 = \omega_0 + J_0 R \sin(\theta - \phi_0) + J_1 [R_c \cos \theta \sin(\theta - \phi_0) + R_s \sin \theta \sin(\theta - \phi_0)]. \tag{6}
\]

Let us study the stationary states of this equation. Since oscillators with a natural frequency \( \omega_0 \) are the most numerous, it is expected that the phases of the order parameters rotate with the frequency \( \omega_0 \) in the stationary states. Thus, we will assume the following relations:

\[
\Theta = \omega_0 t + \Theta', \quad \Theta_c = \omega_0 t + \Theta'_c, \quad \Theta_s = \omega_0 t + \Theta'_s.
\]

Since we are studying stationary states, we will assume that the amplitudes \( R, R_c, R_s \) and the phases \( \Theta', \Theta'_c, \Theta'_s \) tend to constant values as \( t \) goes to infinity. We could assume \( \omega_0 = 0 \) without loss of generality. However, we will retain the term \( \omega_0 \) because the parameters at critical points explicitly contain \( \omega_0 \).

Now, let us derive the SCEs following Kuramoto’s argument. We rewrite the right-hand side of Eq. (6) as

\[
\frac{d}{dt} \phi_0 = \omega_0 - A_0 \sin(\phi_0 - \omega_0 t - \phi_0). \tag{7}
\]

From Eqs. (6) and (7), the following relation is derived:

\[
A_0 e^{i\phi_0} = J_0 R e^{i\Theta} + J_1 [R_c \cos \theta e^{i\Theta'} + R_s \sin \theta e^{i\Theta'}]. \tag{8}
\]

For simplicity, we will omit primes from the phases except for the expressions of \( \omega_0 \) and \( \phi_0' \). \( A_0 \) is expressed as

\[
A_0^2 = (J_0 R)^2 + J_1^2 [R_c \cos \Theta + R_s \sin \Theta]^2 + 2 J_0 J_1 R [R_c \cos(\Theta_c - \Theta) \sin \Theta + R_s \cos(\Theta_s - \Theta) \sin \Theta]. \tag{9}
\]

Since we assume that \( \Theta' \)’s and \( R' \)’s do not depend on time, neither does \( \alpha_0 \). Thus, by defining \( \psi_0 \equiv \phi_0 - \omega_0 t - \phi_0 \), the evolution equation becomes

\[
\frac{d}{dt} \psi_0 = \omega_0 - \omega_0 - A_0 \sin \psi_0. \tag{10}
\]

A. Synchronized oscillators: \([\omega_0 - \omega_0] \leq A_0\)

The stable and unstable solutions are as follows:

**Stable solutions:** \( 0 < \psi_0 < \frac{\pi}{2} \) for \( \omega_0 - \omega_0 > 0 \)

and \(-\frac{\pi}{2} < \psi_0 < 0 \) for \( \omega_0 - \omega_0 > 0 \).

**Unstable solutions:** \( \frac{\pi}{2} < \psi_0 < \pi \) for \( \omega_0 - \omega_0 > 0 \)

and \(-\frac{\pi}{2} < \psi_0 < -\frac{\pi}{2} \) for \( \omega_0 - \omega_0 > 0 \).

The entrained phase \( \psi_0^* \) and number density of the synchronized oscillators with phase \( \psi \) at the location \( \theta \), \( n_s(\theta, \psi) \) are obtained as

\[
\psi_0^* = \sin^{-1}
\left( \frac{\omega_0 - \omega_0}{A_0} \right), \tag{11}
\]

\[
n_s(\theta, \psi) = g(\omega_0 + A_0 \sin \psi) A_0 \cos \psi, \quad |\psi| \leq \frac{\pi}{2}. \tag{12}
\]
where $\sin^{-1}(x)$ is assumed to be the principal value and its range is $[-\frac{\pi}{2}, \frac{\pi}{2}]$.

**B. Desynchronized oscillators: $|\omega_\theta - \omega_0| > A_\theta$**

The solution of Eq. (10) is

$$\psi_\theta(t) = \omega_\theta t + h(\tilde{\omega}_\theta t),$$

where $h(t)$ is a periodic function of $t$ with period $2\pi$. $\tilde{\omega}_\theta$ is the resultant frequency given by

$$\tilde{\omega}_\theta = (\omega_\theta - \omega_0) \sqrt{1 - \left( \frac{A_\theta}{\omega_\theta - \omega_0} \right)^2}.$$

The solution of Eq. (7) is

$$\phi_\theta(t) = \omega_0 t + \psi_\theta(t) + \omega_\theta.$$

Therefore, the resultant frequency $\tilde{\omega}_0$ for $\phi_\theta(t)$ is

$$\tilde{\omega}_0 = \omega_0 + \omega_\theta = \omega_0 + (\omega_\theta - \omega_0) \sqrt{1 - \left( \frac{A_\theta}{\omega_\theta - \omega_0} \right)^2}.$$ (13)

The probability density function of the phase of desynchronized oscillators at location $\theta$, $p_{db}(\theta, \psi)$, obeys the following equation:

$$\frac{\partial}{\partial \psi} \left( (\omega_\theta - \omega_0 - A_\theta \sin \psi) p_{db}(\theta, \psi) \right) = 0.$$ (14)

Solving it yields

$$p_{db}(\theta, \psi) = \frac{|\omega_\theta - \omega_0|}{2\pi |\omega_\theta - \omega_0 - A_\theta \sin \psi|} \times \sqrt{1 - \left( \frac{A_\theta}{\omega_\theta - \omega_0} \right)^2}.$$ (15)

From this, the number density of desynchronized oscillators with phase $\psi$ at $\theta$, $n_{db}(\theta, \psi)$, can be written as

$$n_{db}(\theta, \psi) = \int_{-\infty}^{\infty} g(\omega)|p_{db}(\theta, \psi)|d\omega$$

$$= \frac{1}{\pi} \int_{0}^{\infty} dx x g(\omega_0 + x) \sqrt{x^2 - A_\theta^2} \sin^2 \psi.$$ (16)

**C. Resultant frequency distribution**

We study the resultant frequency distribution for the synchronized and desynchronized oscillators at $\theta$, $G_{sb}(\tilde{\omega}, \theta)$ and $G_{db}(\tilde{\omega}, \theta)$. $G_{sb}(\tilde{\omega}, \theta)$ is

$$G_{sb}(\tilde{\omega}, \theta) = \frac{N_{s,\theta}}{N} \delta(\tilde{\omega} - \omega_0),$$ (16)

where $N_{s,\theta} d\theta$ is the number of synchronized oscillators located in $(\theta, \theta + d\theta)$, and $\delta(x)$ is the Dirac delta. $G_{db}(\tilde{\omega}, \theta)$ is expressed as

$$G_{db}(\tilde{\omega}, \theta) = \frac{|\tilde{\omega} - \omega_0|}{\sqrt{(\tilde{\omega} - \omega_0)^2 + A_\theta^2}} g\left[ \omega_0 + \sqrt{(\tilde{\omega} - \omega_0)^2 + A_\theta^2} \right].$$ (17)

The following relation is used in the derivation:

$$\omega_0 = \omega_0 + (\tilde{\omega}_0 - \omega_0) \sqrt{1 + \left( \frac{A_\theta}{\omega_0 - \omega_0} \right)^2}.$$ (18)

**D. SCEs, auxiliary equations, and solutions of auxiliary equations**

In this subsection, we state the SCEs, the auxiliary equations, and the solutions of the auxiliary equations. Their derivations are in Appendix A.

Here, we will introduce the following notation:

$$\langle B \rangle = \frac{1}{Z} \int_{0}^{\pi/2} d\psi \int_{0}^{2\pi} d\theta g(\omega_0 + A_\theta \sin \psi) \cos^2 \psi B,$$ (19)

$$Z = \frac{1}{\pi} \int_{0}^{\pi/2} d\psi \int_{0}^{2\pi} d\theta g(\omega_0 + A_\theta \sin \psi) \cos^2 \psi.$$ (20)

The SCEs are

$$R = (J_0 R + J_1 R_c \cos(\theta_c - \theta)) Z,$$ (21)

$$R_c = (J_0 R \cos(\theta_c - \theta) + J_1 R_c \cos^2(\theta_c - \theta)) Z,$$ (22)

and

$$R_c = (J_0 R \sin(\theta_c - \theta) + J_1 R_c \sin(\theta_c \cos \theta)) \cos(\theta_c - \theta) + R_c \sin(\theta_c \cos \theta) \cos(\theta_c - \theta) Z.$$ (23)

The auxiliary equations are

$$R_c \sin(\theta_c - \theta) + R_c \sin(\theta_c \cos \theta) \sin(\theta_c - \theta) = 0,$$ (24)

$$J_0 R \cos(\theta_c - \theta) \sin(\theta_c - \theta) + J_1 R_c \sin(\theta_c \cos \theta) \sin(\theta_c - \theta) = 0,$$ (25)

$$J_0 R \sin(\theta_c - \theta) - J_1 R_c \sin(\theta_c \cos \theta) \sin(\theta_c - \theta) = 0.$$ (26)

Two of the auxiliary equations are independent. Thus, the phases of the complex order parameters are completely determined from the auxiliary equations. We list their solutions below.

(i) $R = 0, R_1 = \sqrt{R_c^2 + R_c^2} \neq 0, \cos(\theta_c - \theta) = 0$, that is, $\theta_c - \theta \equiv \pm \frac{\pi}{2} \text{ (mod } 2\pi\text{)}$. This corresponds to the stable spinning ($S$) solution.

(ii) $R \neq 0, R_1 \neq 0$.

A solution of $\sin(\theta_c - \theta) = 0$ and $\cos(\theta_c - \theta) = 0$, that is, $\theta_c - \theta \equiv \pm \frac{\pi}{2} \text{ (mod } 2\pi\text{)}$. This corresponds to the stable pendulum ($Pn$) solution.

B solution of $\sin(\theta_c - \theta) = 0$ and $\cos(\theta_c - \theta) = 0$, that is, $\theta_c - \theta \equiv \pm \frac{\pi}{2} \text{ (mod } 2\pi\text{)}$. This corresponds to the unstable $Pn$ solution.

Hereafter, we omit “(mod $2\pi$)” for simplicity.

**III. CHARACTERIZATION OF THE SOLUTIONS**

The preceding section determined the phases of the order parameters from the auxiliary equations. Furthermore,
IV. SELF-CONSISTENT EQUATIONS FOR ORDERED SOLUTIONS

This section uses the same notation as in Sec. II; that is, \( \Theta \)'s denote \( \Theta \)'s. We give the SCEs and relevant quantities of various solutions of the SCEs. The derivations are given in Appendix B.

A. Stable U solution

In the \( U \) solution, \( R_1 = 0 \). This is merely the solution of the Kuramoto model,

\[
R = 2J_0R_1 \int_0^{\pi/2} d\psi \, g(\omega_0 + J_0 R \sin \psi) \cos^2 \psi,
\]

\[
A_0 = J_0 R_1, \quad \alpha_0 = \Theta' = \text{const},
\]

\[
\phi_0^* = \omega_0 t + \Theta' + \sin^{-1} \left( \frac{\omega_0 - \omega_0}{J_0 R_1} \right).
\]

The phase transition point from the \( P \) phase to the \( U \) phase is

\[
J_{0, c} = \frac{2}{\pi g(\omega_0)}.
\]

B. Stable S solution

For the stable \( S \) solution, \( R = 0 \), \( \langle \cos \theta \rangle = \langle \sin \theta \rangle = 0 \), and \( \Theta_c - \Theta_s = \pm \pi/2 \).

\[
R_c = J_1 R_1 \int_0^{\pi/2} d\psi \, g(\omega_0 + J_1 R_c \sin \psi) \cos^2 \psi,
\]

\[
A_0 = J_1 R_c, \quad \alpha_0 = \Theta'_c = \text{const},
\]

\[
\phi_0^* = \omega_0 t + \sin^{-1} \left( \frac{\omega_0 - \omega_0}{J_1 R_c} \right) + \Theta'_c + \theta.
\]

The phase transition point from the \( P \) phase to the \( S \) phase and the order parameter \( R_1 \) near the transition point are

FIG. 1. \( \theta \) dependencies of entrained phase \( \phi_0^* \). Line plots: theory; +: simulation \((N = 10000, \sigma = 0.2, J_0 = 1.2J_{0, c}, \omega_0 = 0) \). Since \( \omega_0 \) is 0, the theoretical values are calculated by using Eq. (11). These values are connected by straight lines so that it is easier to compare them with the numerical results. Only 1% of the entrained phases are depicted. (a) \( U \) solution, \( J_1/J_0 = 1.9 \); (b) \( S \) solution, \( J_1/J_0 = 2.1 \); (c) \( Pn \) solution, \( J_1/J_0 = 2.1 \).
given by
\[ J_{1,c} = \frac{4}{g(\omega_0) \pi} = 2J_{0,c}, \]  
\[ R_1 \approx \frac{4}{J_{1,c}} \left( \frac{2(J_1 - J_{1,c})}{\pi [g'(\omega_0)]} \right)^2 \alpha \sqrt{J_1 - J_{1,c}}. \]  
(30)

When \( g(\omega) \) is a Gaussian distribution with mean \( \omega_0 \) and standard deviation \( \sigma \), \( J_{0,c} \) and \( J_{1,c} \) become
\[ J_{0,c} = 2 \sqrt{\frac{\pi}{N}} \sigma, \quad J_{1,c} = 4 \sqrt{\frac{\pi}{N}} \sigma = 2J_{0,c}. \] 

The entrained phase \( \phi^*_c \) linearly depends on \( \theta \). Since the resultant frequency distributions for the synchronized and desynchronized oscillators do not depend on \( \theta \), we denote them by \( G_s(\phi) \) and \( G_d(\phi) \), respectively,
\[ G_s(\phi) = \frac{N_c}{N} \delta(\phi - \omega_0), \]  
\[ G_d(\phi) = \frac{\sqrt{(\phi - \omega_0)^2 + (J_1 R_c)^2}}{g(\omega_0 + \sqrt{(\phi - \omega_0)^2 + (J_1 R_c)^2})}. \]  
(31)

where \( N_c \) is the number of synchronized oscillators.

C. Stable \( Pn \) solution

We define the phase \( \psi \) of \( (R_c, R_s) \) as
\[ R_c = R_1 \cos \psi, \quad R_s = R_1 \sin \psi. \]

Furthermore, defining \( \tilde{\alpha}_0 = \alpha_0 - \Theta_c \), we have
\[ A_\theta \cos \tilde{\alpha}_0 = J_1 R_1 \cos(\theta - \psi \cos(\Theta_c - \Theta_c)), \]  
\[ A_\theta \sin \tilde{\alpha}_0 = -J_1 R_1 \sin(\Theta_c - \Theta_c), \]  
\[ A_\theta = \sqrt{(J_0 R_1)^2 + (J_1 R_1)^2 \cos^2(\theta - \psi \cos(\Theta_c - \Theta_c))}, \]  
(33)

where \( \sin(\Theta_c - \Theta_c) = \pm 1 \) and \( \cos(\Theta_c - \Theta_c) = \pm 1 \). By transforming \( \theta \) into \( \theta' = \theta - \psi \cos(\Theta_c - \Theta_c) \), the SCEs become
\[ R = \frac{4J_0 R_1}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi/2} d\theta' g(\omega_0 + A_{\theta' + \psi \cos(\Theta_c - \Theta_c)} \sin \psi) \cos^2 \psi, \]  
(34)
\[ R_1 = \frac{4J_1 R_1}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi/2} d\theta' g(\omega_0 + A_{\theta' + \psi \cos(\Theta_c - \Theta_c)} \sin \psi) \cos^2 \psi \cos^2 \theta', \]  
(35)
\[ A_{\theta' + \psi \cos(\Theta_c - \Theta_c)} = \sqrt{(J_0 R_1)^2 + (J_1 R_1)^2 \cos^2 \theta'}, \]  
\[ \phi^* = \omega_0 \tilde{\alpha}_0 + \psi + \sin^{-1} \left( \frac{\omega_0 - \omega_0}{A_\theta} \right) \]
\[ = \omega_0 \tilde{\alpha}_0 + \Theta^*_c + \sin^{-1} \left( \frac{\omega_0 - \omega_0}{A_\theta} \right). \]  
(37)

In the preceding equation, \( \theta \) is the original coordinate and \( A_\theta \) is given by Eq. (33). From (37), the rotation number is 0. Using this \( A_\theta \), the resultant frequency distributions \( G_s(\phi, \tilde{\alpha}_0) \) and \( G_d(\phi, \tilde{\alpha}_0) \) are given by Eqs. (16) and (17).

D. Unstable \( Pn \) solution

Setting \( \tilde{\alpha}_0 = \alpha_0 - \Theta_c \), we have
\[ A_\theta \sin \tilde{\alpha}_0 = -J_1 R_1 \sin \theta \sin(\Theta_c - \Theta_c), \]  
\[ A_\theta \cos \tilde{\alpha}_0 = J_0 R_1 \cos(\Theta_c - \Theta_c) + J_1 R_1 \cos \theta, \]  
\[ A_\theta = \sqrt{J_0 R_1 \cos(\Theta_c - \Theta_c) + J_1 R_1 \cos \theta)^2 + (J_1 R_1 \sin \theta)^2. \]

By transforming \( \theta \) into \( \theta' = \theta - (\Theta_c - \Theta_c) \), Eqs. (21), (22), and (23) become
\[ R = \frac{2}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi/2} d\theta' g(\omega_0 + A_{\theta' + \psi \cos(\Theta_c - \Theta_c)} \sin \psi) \cos^2 \psi \times (J_0 R + J_1 R_c \cos \theta'), \]  
(38)
\[ R_1 = \frac{2}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi/2} d\theta' g(\omega_0 + A_{\theta' + \psi \cos(\Theta_c - \Theta_c)} \sin \psi) \cos^2 \psi \times (J_0 R + J_1 R_c \cos \theta'), \]  
(39)
\[ R_s = J_1 R_2 \frac{2}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi/2} d\theta' g(\omega_0 + A_{\theta' + \psi \cos(\Theta_c - \Theta_c)} \sin \psi) \cos^2 \psi \sin^2 \theta', \]  
(40)

where \( A_{\theta' + \psi \cos(\Theta_c - \Theta_c)} = \sqrt{(J_0 R_1 + J_1 R_c \cos \theta')^2 + (J_1 R_1 \sin \theta')^2. \]

By numerically solving Eqs. (34) and (35) for the stable \( Pn \) solution, we obtain the \( U \) solution by setting \( R_1 = 0 \) and the stable \( Pn \) solution by setting \( R_1 \neq 0 \). This is because Eq. (34) with \( R_1 = 0 \) reduces to the SCE (27) for the \( U \) solution. A necessary condition to obtain a stable \( Pn \) solution is \( J_1 > 2J_0 \). We prove this in Appendix C.

V. PHASE DIAGRAM AND BIFURCATION STRUCTURE

Figure 2(a) is the phase diagram in scaled parameter space \((J_0/\sigma, J_1/\sigma)\). Here, \( \sigma \) is the standard deviation of the Gaussian distribution \( g(\omega) \) that was used in the simulations. The diagram shows that the \( S \) and \( U \) solutions can coexist and the \( S \) and \( Pn \) solutions can coexist. Figure 2(b) shows the \( J_1/\sigma \) dependencies of the order parameters \( R \) and \( R_1 \) with \( J_0/\sigma \) fixed to 4. From this figure, we can see that the \( Pn \) solution bifurcates from the \( U \) solution continuously, as is proved in Appendix C. On the other hand, the \( S \) solution bifurcates from the \( P \) solution at the critical value of \( J_1/\sigma \). Furthermore, the unstable \( Pn \) solution and stable \( S \) solution merge and the stable \( S \) solution becomes unstable as \( J_1/\sigma \) decreases, and the unstable and stable \( Pn \) solutions merge and the stable \( Pn \) solution becomes unstable as \( J_1/\sigma \) increases. Therefore, the unstable \( Pn \) solution determines the boundary of the coexistent regions of the \( S \) and \( U \) solutions and of the \( S \) and \( Pn \) solutions. Taking into account these observations, we can derive the boundaries of the coexisting solutions by using the unstable \( Pn \) solution and relevant stable solutions. The equations for the boundaries are derived in Appendix D.

VI. NUMERICAL RESULTS

We performed numerical simulations using a Gaussian distribution with mean 0 and standard deviation \( \sigma \) as \( g(\omega) \). That is, \( \omega_0 = 0 \). If \( J_0 \) or \( J_1 \) is large in the calculation, the discretization of \( \omega_0 \) by the Euler method, \( \phi(\omega_0 + a\omega_0 - \phi(\theta))^k \), becomes worse [6]. Since the evolution equations with the same values
of \( \omega_0/\sigma \), \( J_0/\sigma \), and \( J_1/\sigma \) become identical by changing the time scale from \( \tau \) to \( \sigma \tau \), we fix \( J_0 \) or \( J_1 \) and change \( \sigma \) when \( J_0 \) or \( J_1 \) is large. The Euler method had a time increment \( h = 0.1 \).

A. Phase diagram

Figure 2(a) depicts the theoretically and numerically obtained boundaries. The theoretical results (the solid curves) are in good agreement with the simulation results (symbols). Now, let us examine the physical meanings of the phase transitions by using the rotation numbers of the solutions. There are five boundaries in the phase diagram shown in Fig. 2(a). The transition from the \( P \) to \( U \) phase takes place continuously at \( J_0/\sigma = (J_0/\sigma)_c \), for \( 0 \leq J_1/\sigma \leq (J_1/\sigma)_c \), and this is the same transition as in the Kuramoto model. The transition from the \( P \) to \( S \) phase takes place continuously at \( J_1/\sigma = (J_1/\sigma)_c \equiv 2(J_0/\sigma)_c \), for \( 0 \leq J_0/\sigma \leq (J_0/\sigma)_c \). In the \( P \) phase, there are no synchronized oscillators and the rotation number is not defined. In the \( S \) phase, the rotation number is 1. The above illustrates that a solution with a nonzero rotation number can appear from a solution in which the rotation number is not defined. Another example of this occurs in model 2 (see Sec. VIII). That is, the \( S_m \) solution with the rotation number \( \pm m \) appears from the \( P \) solution when the \( m \)th Fourier component exists in the interaction. The transition from the \( U \) to \( Pn \) phase takes place continuously at \( J_1/\sigma = 2J_0/\sigma \) for \( J_0/\sigma \geq (J_0/\sigma)_c \), and \( J_1/\sigma \geq (J_1/\sigma)_c \). In this case, the rotation number of the \( U \) and \( Pn \) phases is 0. This is reasonable because the transition is continuous and synchronized oscillators exist in both phases. Although both solutions have the same rotation number, 0, they are different. That is, as is shown in Figs. 1(a) and 1(c), the directions of the two synchronized oscillators do not correlate in the \( U \) phase, but they correlate weakly in the \( Pn \) phase. Now, let us investigate the transitions at the bistable region boundaries. As mentioned in the previous section, the stable \( S \) and unstable \( Pn \) solutions merge and the stable \( S \) solution disappears at the boundary between the \( S \) and \( U \) solutions, and the stable \( Pn \) and unstable \( Pn \) solutions merge and the stable \( Pn \) solution disappears at the boundary between the \( S \) and \( Pn \) solutions. This type of transition does not exist in the Kuramoto model. When the stable \( S \) solution with rotation number \( \pm 1 \) and the unstable \( Pn \) solution merge, these two solutions should have the same rotation number, \( \pm 1 \). Likewise, when the stable \( Pn \) solution with rotation number 0 and the unstable \( Pn \) solution merge, their rotation numbers should be 0. Thus, the rotation number of the unstable \( Pn \) solution changes from \( \pm 1 \) to 0 as \( J_1/\sigma \) increases. This is really the case, as evidenced by Fig. 3. When we calculated \( \phi_\omega^* \) for the unstable solution, we assumed \( \Theta_c = 0 \), \( \Theta_c - \Theta = 0 \), and \( \Theta_c - \Theta = \pi/2 \), and we fixed these values when values of \( J_1/\sigma \) change, because these phases take on discrete values and are considered to be continuous with respect to the system parameters. The reason why the rotation number can change as a system parameter changes is as follows. Oscillators are discretely spread out on a circle and the difference between the phases of the neighboring synchronized oscillators can become \( \pi \). Since the phase difference is defined in mod \( 2\pi \), if it changes and takes on the value \( \pi \), the rotation number will change by \( \pm 1 \). The rotation number is not defined if there are neighboring synchronized oscillators whose phases differ by \( \pi \). However, this situation is very special. In most cases, it is defined and can be used to classify solutions and get physical information on them.

B. Spinning solution

Figures 4(a) and 4(b) plot the dependence of \( R_1 \) and the distribution of the resultant frequencies \( G(\tilde{\omega}) \) on \( \sigma \). The location-dependent entrained phase \( \phi_\omega^* \) is in Fig. 1(b). It turns out that the entrained phase depends linearly on \( \theta \) in the \( S \) solution but takes on random values for the \( U \) solution [see Fig. 1(b)], as theoretically expected. All of the numerical results agree quite well with the theoretical results.

C. Pendulum solution

Figure 5 displays the theoretical and simulated results of the \( J_0 \) dependence of the order parameters for \( J_1 = 2.1J_0 \).
FIG. 3. Theoretical estimation of θ dependencies of phases \( \phi_{\theta}^* \) for unstable \( Pn \) solution. \( \sigma = 0.2, J_0/\sigma = 4 \). The theoretical values are calculated using a similar equation to Eq. (11) for the unstable \( Pn \) solution, and these values are connected by straight lines. Only 1% of the phases are depicted. (a) \( J_1/\sigma = 6 \), near the boundary of the region in which the \( S \) and \( U \) phases coexist; (b) \( J_1/\sigma = 8 \), at the boundary of the region in which the \( S \) and \( U \) phases coexist; (c) \( J_1/\sigma = 10 \), near the boundary of the region in which the \( S \) and \( Pn \) phases coexist.

Theoretical and simulation results of the location-dependent resultant frequency distribution \( G(\tilde{\omega},\theta) \) for different \( \theta \) are in Fig. 6, and those of the \( \theta \) dependencies of the entrained phases \( \phi_{\theta}^* \) are in Fig. 1(c). The agreement between the theoretical and numerical results is excellent. To investigate the desynchronized oscillators, we constructed a Lorenz plot of the time series \( \sin\phi_i(t) \) for the \( Pn \) solution (Fig. 7).

The Lorenz plot is a mapping from the difference \( \Delta t = t_{i+1} - t_i \) to \( \Delta t_{i+1} \), where \( t_i \) and \( t_{i+1} \) are successive times that satisfy \( \cos[\phi_i(t_i)] = 1 \) and \( \cos[\phi_i(t_{i+1})] = 1 \), respectively. As shown in Fig. 7, the simulation results are scattered in the Lorenz plot. This indicates that the trajectory of a desynchronized oscillator behaves chaotically even though theoretically it is quasiperiodic. However, this is reasonable because synchronized and desynchronized oscillators interact with other oscillators, and desynchronized oscillators are easily influenced by perturbations, whereas entrained oscillators are forced to lock to the fixed phases. As is well known, quasiperiodic motion with more than two dimensions generically becomes chaotic through perturbation \cite{28}. In most of our numerical results, e.g., those for the resultant frequency distribution, the larger \( N \) is, the better the agreement between the theoretical and numerical results becomes. These results suggest that the system behaves quasiperiodically as \( N \) goes to infinity.

VII. SYSTEM WITH INTERACTION COMPOSED OF FIRST AND SECOND FOURIER COMPONENTS

In this section, we study model 2, in which the interaction is given by

\[
J_{0,0'} = \frac{1}{N} \left[ J_m \cos[m(\theta - \theta')] + J_n \cos[n(\theta - \theta')] \right],
\]

(41)

FIG. 4. (a) \( \sigma/J_1 \) dependence of \( R_i \), \( \sigma/J_1 = (\sigma/J_1), i = 0.1, 0.2, \ldots, 1.2 \). We set \( J_0 = 0 \) and \( J_1 = 1 \) and change \( \sigma \). We set \( \omega_0 = 0 \). Dashed curve: theory. Symbols: simulation. \( N = 20000 \). The sample average was taken over 20 initial configurations. Vertical lines are error bars. (b) The distribution of the resultant frequencies \( G(\tilde{\omega}) \) in the ordered phase calculated for a sample. \( N = 100000 \). Solid curve: theory. Symbols: simulation. \( J_0 = 0, J_1 = 1 \). \( \sigma/J_1 = (\sigma/J_1), 0.9 \).
The order parameters are defined as curve and theory, symbols: simulation. $N$ is given by $m^2$ where $n$ is constant and $/\Theta 1 k_c$. The evolution equation becomes

\[
\frac{d}{dt} \psi = \phi_0 - \omega_0 t - \Phi 0, \quad \text{(45)}
\]

For later use, we define $R_k$ and $\psi_k$ by $R_k = i R_k e^{ik \psi_k}$. In the next subsections, we give the SCE for the stable spinning and pendulum solutions. The derivations are in Appendix E. Below, for simplicity, we will omit primes from the phases except for the expressions of $\alpha_0$ and $\Phi 0$.

A. Spinning solution

We give the conditions and SCEs for the stable spinning solution with $R_m > 0$ and $R_n = 0$. We denote the solution by $S_m$. The conditions on this solution are $\cos(\Theta_{mc} - \Theta_{ms}) = 0$ and $\cos(2m \Phi_m) = 0$. From this, $R_{mc} = R_{ms} = \frac{1}{2} R_1$ and $A_0 = J_m R_{mc}$ follow. The SCE is

\[
1 = J_m \int_0^{\pi/2} d \psi g(\omega_0 + J_m R_{mc} \sin \psi) \cos^2 \psi. \quad (46)
\]

FIG. 6. Theoretical and simulated results for the distribution $G(\omega, \theta)$ of the resultant frequencies for the $Pn$ solution. Curve: theory; + : simulation $(N = 100000, \sigma = 0.2, J_1/J_0 = 2.1, J_0 = 1.2 J_0)$. (a) $\theta = 0.05 \times 2 \pi$, (b) $\theta = 0.25 \times 2 \pi$.
This equation is the same as Eq. (29) for the stable spinning solution studied in model 1. The critical point is given by

\[ J_m^{(c)} = J_1^{(c)} = \frac{4}{\pi g(\alpha_0)} = 2J_0^{(c)}. \]  

(47)

That is, the critical point for \( S_m \) is the same as the one for the \( S \) solution in model 1. The synchronized solution is expressed as

\[ \alpha_0 = \Theta_1' \mp m\theta, \]

\[ \phi^*_n = \omega_0 t + \psi_0' + \alpha_0 \]

\[ = \omega_0 t + \sin^{-1} \left( \frac{\alpha_0 - \alpha_0}{J_m R_m} \right) + \Theta_1' \mp m\theta. \]  

(48)

The entrained phase of the solution changes by \( \pm 2\pi m \) when the location \( \theta \) changes by \( 2\pi \); that is, its rotation number is \( \pm m \).

**B. Pendulum solution**

Here, we assume \( R_m R_s \neq 0 \). Moreover, for simplicity, we assume \( n \neq 3m \). Accordingly, the conditions on the stable \( Pn \) solution are

\[ \sin(\Theta_{mc} - \Theta_{ms}) = 0, \quad \sin(\Theta_{nc} - \Theta_{ms}) = 0, \]

\[ \cos(\Theta_{nc} - \Theta_{ms}) = 0. \]  

(49)

Here, we define

\[ \tilde{\theta}_k = \varphi_k e^{i(\Theta_{kc} - \Theta_{kc})}, \]

\[ \tilde{\theta} = \tilde{\theta}_0 - \tilde{\theta}_m, \quad \theta' = \tilde{\theta} - \tilde{\theta}_m, \]

from which we obtain

\[ A_\theta = A_{\theta' + \theta_m} \]

\[ = \sqrt{[J_m R_m \cos(m\theta')]^2 + [J_s R_s \cos(n(\theta' - \tilde{\theta})]}. \]  

(50)

By changing the variable from \( \theta \) to \( \theta' \), the SCEs become

\[ 1 = \int_0^{\pi/2} d\psi \int_0^{2\pi} d\theta' g(\phi_0 + A_{\theta' + \theta_m} \sin \psi) \]

\[ \times \sin \psi \cos^2 (m\theta'), \]  

(51)

\[ 1 = \int_0^{\pi/2} d\psi \int_0^{2\pi} d\theta' g(\phi_0 + A_{\theta' + \theta_m} \sin \psi) \]

\[ \times \sin \psi \cos^2 [n(\theta' - \tilde{\theta})]. \]  

(52)

Furthermore, we derive the condition

\[ \langle \sin(2n(\theta' - \tilde{\theta})) \rangle = 0. \]  

(53)

The sufficient condition for this is \( \cos(2n\tilde{\theta}) = 0 \) or \( \sin(2n\tilde{\theta}) = 0 \), and it determines the value of \( \tilde{\theta} \). Setting \( \tilde{\alpha}_0 = \alpha_0 - \Theta_{ms} \), we obtain

\[ A_\theta \cos \tilde{\alpha}_0 = J_m R_m \cos(\Theta_{mc} - \Theta_{ms}) \cos(m\theta'), \]

\[ A_\theta \sin \tilde{\alpha}_0 = J_s R_s \sin(\Theta_{nc} - \Theta_{ms}) \cos(n(\theta' - \tilde{\theta})). \]  

(54)

Thus,

\[ \phi^*_n = \omega_0 t + \sin^{-1} \left( \frac{\alpha_0 - \omega_0}{A_\theta} \right) + \tilde{\alpha}_0 + \Theta_1'. \]

(56)

This formula indicates that the rotation number can take on values of \( 0, \pm 1, \ldots, \pm m \).

**C. Numerical results**

We performed numerical simulations in which we used a Gaussian distribution for \( g(\alpha) \). We set the mean to be 0, i.e., \( \alpha_0 = 0 \) and standard deviation \( \sigma \). We studied the case of \( m = 1 \) and \( n = 2 \). Figure 8 plots the time series of the amplitudes of the complex order parameters for \( S_1 \), \( S_2 \), and \( Pn \). The trajectories of the amplitudes of the complex order parameters for \( S_1 \) and \( S_2 \) converge, but those for \( Pn \) fluctuate. Figure 9 shows the time series of the amplitudes of the complex order parameters and \( 4\tilde{\theta} \). Moreover, Figs. 10 and 11, respectively, display the \( J_2 \) dependence of the order parameters for \( J_1 = J_2 \) and the \( \theta \) dependencies of the entrained phases \( \phi^*_n \). The rotation numbers for the \( S_1 \), \( S_2 \), and \( Pn \) solutions are \( -1, 2, \) and 0, respectively. The theoretical and numerical results agree quite well. Figure 12 shows the resultant frequency distribution \( G(\omega) \) of the \( S_1 \) and \( S_2 \) solutions, and the location-dependent resultant frequency distribution \( G(\omega, \theta) \) for different \( \theta \) of the \( Pn \) solution. Agreement between numerical and theoretical results is excellent for the \( S_1 \) and \( S_2 \) solutions. However, it is not close for the \( Pn \) solution. This is because the trajectories of \( R_1 \) and \( R_2 \) for the \( Pn \) solution fluctuate, as shown in Fig. 8(c). As can be seen from Fig. 9, \( \Theta_1 - \Theta_{1s} = -\pi, \Theta_2 - \Theta_{2s} = 0, \Theta_{2s} - \Theta_{1s} = -\pi/2 \). Thus, \( \tilde{\theta}_1 = -\psi_1 \) and \( \tilde{\theta}_2 = \psi_2 \). Therefore, \( 0 \leq 4\tilde{\theta} \leq 3\pi \). Accordingly,
the condition \(\cos(4\hat{\theta}) = 0\) implies \(4\hat{\theta} = \frac{\pi}{2}, \frac{3\pi}{2}, \frac{5\pi}{2}\). The other condition \(\sin(4\hat{\theta}) = 0\) implies \(4\hat{\theta} = 0, \pi, 2\pi, 3\pi\). However, numerical results show that \(4\hat{\theta} \approx 2.2\pi\) [Fig. 9(c)]. This is the cause of the discrepancy between the theoretical and numerical results for \(G(\hat{\omega}, \theta)\).

VIII. SUMMARY AND DISCUSSION

We studied phase oscillator networks on a circle with two types of interaction (models 1 and 2).

Model 1 is the Mexican-hat interaction. The interaction is composed of two terms, one of which is a uniform interaction with strength \(J_0\), and the other is a sinusoidal interaction with respect to the location \(\theta\) of oscillators with strength \(J_1\). If \(J_1 = 0\), the present model reduces to the Kuramoto model. To obtain self-consistent equations, information about the differences between the phases of the complex order parameters is necessary. Previously, for this purpose, we studied the classical \(XY\) model to which the phase oscillator network reduces when all oscillators have the same natural frequency [29,30]. The relevant order parameters are the same in the oscillator network and the \(XY\) model. The order parameters that characterize the solutions are \(R\) and \(\hat{R}_1\). The saddle point equations (SPEs) for the \(XY\) model were obtained and the differences between the phases of the complex order parameters were determined analytically [30]. So far, we have used information on the phases of the complex order parameters in the \(XY\) model to solve the SCEs for the phase oscillator network. Recently, we succeeded in deriving auxiliary equations that determine the phases of the order parameters for the phase oscillator network. The auxiliary equations turned out to be the same as the SPEs for the phases of the complex order parameters in the \(XY\) model [26]. In this paper, we gave detailed derivations of the relevant equations and quantities. We derived two auxiliary equations by expressing the order parameters in terms of the number density of the oscillators. We used them to analytically determine the phases of the order parameters, derived self-consistent equations for their amplitudes, and obtained three nontrivial solutions that are characterized by the order parameters and the rotation numbers of the synchronized oscillators \(X_0^*\). We drew the phase diagram by using formulas for the phase boundaries derived using the unstable \(Pn\) solution. Furthermore, we found that the disappearance of coexistent regions between the \(U\) and \(S\) solutions and between the \(Pn\) and \(S\) solutions is due to annihilation of the unstable \(Pn\) and stable \(S\) solutions, and that of the unstable and stable \(Pn\) solutions. This type of transition does not exist in the Kuramoto model. We also analytically obtained the location-dependent distribution of the resultant frequencies and entrained phases and validated the theoretical results by simulation, except for the chaotic behavior of the desynchronized oscillators. This chaotic behavior is quite reasonable because quasiperiodic motion with more than two dimensions generically becomes chaotic through perturbation.
Our numerical results suggest that the system behaves quasiperiodically as $N$ goes to infinity.

Model 2 is an interaction including the $m$th and $n$th Fourier components, where $m < n$. We found spinning solutions, $S_m$

FIG. 11. $\theta$ dependencies of entrained phases $\phi_0^*$. Line plots: theory; +: simulation. The theoretical values are calculated using Eq. (56) with $\omega_0 = 0$, and these values are connected by straight lines so that it is easier to compare them with the numerical results. Only 1% of the entrained phases are depicted. $J_1 = J_2 = 1.8J_{1,c}, \sigma = 0.2$. Simulation: $N = 10,000$. (a) $S_1$ solution. (b) $S_2$ solution. (c) $Pn$ solution.

FIG. 12. Theoretical and simulated results for the distribution of the resultant frequencies. $G(\tilde{\omega})$ for the $S_1$ and $S_2$ solutions and $G(\tilde{\omega}, \theta)$ for the $Pn$ solution. Curve: theory, +: simulation ($N = 200,000, \sigma = 0.01, J_1 = J_2 = 1.2J_{1,c}$). (a) $S_1$ solution, (b) $S_2$ solution, (c) $\theta = 0.05 \times 2\pi$ for $Pn$ solution, (d) $\theta = 0.25 \times 2\pi$ for $Pn$ solution.
and $S_m$ and a pendulum solution. The critical points for the $S_m$ and $S_n$ solutions are the same as those for the $S$ solution in model 1. In $S_m$ ($S_n$), the phase of the entrained oscillators changes by $\pm 2m \pi$ ($\pm 2n \pi$) when the location changes by $2\pi$. That is, the rotation number is $\pm m$ ($\pm n$). On the other hand, in the pendulum solution, the phase of the entrained oscillators fluctuates when location changes by $2\pi$, and the rotation number can take on values of $0, \pm 1, \pm 2, \ldots, \pm m$. We performed a similar analysis to that of model 1 for $m = 1$ and $n = 2$. In the $J_1, J_2$ space, around the line $J_1 = J_2$, these three solutions coexist for $J_1 > J_1'$ and $J_2 > J_2'$. We conducted a simulation that validated the theoretical results for the $J_2$ dependencies of $R_1$ and $R_2$ and the dependencies of the entrained phases on location. As for the distribution of the resultant frequencies, the agreement between the theoretical and numerical results was excellent for the $S_1$ and $S_2$ solutions. However, theoretical and numerical results for the location-dependent distribution of the resultant frequencies did not agree very well for the $P_0$ solution. This is because the trajectories of $R_1$ and $R_2$ for the $P_0$ solution fluctuate, and the numerical value of $\bar{\theta}$ deviates from the theoretical prediction. The reason for this deviation seems to be that the desynchronized oscillators behave more chaotically in the $P_0$ solution than in the $S_1$ and $S_2$ solutions.

How the existing phases and phase transitions depend on the type of interaction is an interesting question. The present method is applicable to phase oscillator networks not only on a circle but also in general spaces. For example, we have found that there are different phases and phase transitions from those in the Mexican-hat interaction.

ACKNOWLEDGMENT

We are grateful to Chie Izumi for performing numerical simulations of model 2 in the early stage of the present work.

APPENDIX A: DERIVATION OF AUXILIARY EQUATIONS AND SCEs, AND SOLUTIONS OF AUXILIARY EQUATIONS

The total number density of oscillators with phase $\psi$ at location $\theta$, $n(\theta, \psi)$, is $n(\theta, \psi) = n_1(\theta, \psi) + n_2(\theta, \psi)$. From Eq. (15), since $n_{\theta\psi}(\theta, \psi + \pi) = n_{\theta\psi}(\theta, \psi)$, $\frac{\partial}{\partial t} n_{\theta\psi}(\theta, \psi)e^{i\psi} d\psi = 0$ follows. Thus, only synchronized oscillators contribute to the order parameters:

$$R e^{i\psi} = \int_{-\pi}^{\pi} d\psi n_1(\psi)e^{i\psi + i\alpha_0}, \tag{A1}$$

$$R e^{i\theta \psi} = \int_{-\pi}^{\pi} d\psi \left\{ \frac{1}{2\pi} \int_{0}^{2\pi} d\theta n_1(\theta, \psi) \cos \theta e^{i\psi + i\alpha_0} \right\}, \tag{A2}$$

$$R e^{i\theta \psi} = \int_{-\pi}^{\pi} d\psi \left\{ \frac{1}{2\pi} \int_{0}^{2\pi} d\theta n_1(\theta, \psi) \sin \theta e^{i\psi + i\alpha_0} \right\}, \tag{A3}$$

where

$$n_1(\psi) = \frac{1}{2\pi} \int_{0}^{2\pi} d\theta n_1(\theta, \psi).$$

By substituting the expression of $n_1(\theta, \psi)$ into Eq. (A1), we obtain the following equations:

$$R = \frac{1}{\pi} \int_{0}^{\pi/2} d\psi \int_{0}^{2\pi} d\theta g(\omega_0 + A_\theta \sin \psi) \cos^2 \psi \times \left\{ J_0 R + J_1 (R_c \cos \theta e^{i(\theta_\psi - \theta)}) + R_s \sin \theta e^{i(\theta_\psi - \theta)} \right\}. \tag{A4}$$

$A_\theta$ is expressed as

$$A_\theta^2 = (J_0 R)^2 + J_1^2 (R_c \cos \theta)^2 + (R_s \sin \theta)^2 \times + 2R_c R_s \cos (\Theta - \Theta_s) \sin \theta \cos \theta \times + 2J_0 J_1 R (R_c \cos (\Theta - \Theta) \cos \theta \times + R_s \cos (\Theta - \Theta) \sin \theta).$$

We introduce the following notation:

$$\langle B \rangle \equiv \frac{1}{Z} \int_{0}^{\pi/2} d\psi \int_{0}^{2\pi} d\theta g(\omega_0 + A_\theta \sin \psi) \cos^2 \psi \times B, \tag{A5}$$

$$Z = \int_{\pi/2}^{\pi/2} d\psi \int_{0}^{2\pi} d\theta g(\omega_0 + A_\theta \sin \psi) \sin^2 \psi. \tag{A6}$$

Equation (A4) can be rewritten as

$$R = (J_0 R + J_1 (R_c e^{i(\theta_\psi - \theta)} \cos \theta) + R_s e^{i(\theta_\psi - \theta)} \langle \sin \theta \rangle) Z. \tag{A7}$$

Similarly, Eqs. (A2), and (A3) can be rewritten as

$$R_c = (J_0 R e^{-i(\theta_\psi - \theta)} \cos \theta) + J_1 (R_c \cos \theta) \times + R_s e^{-i(\theta_\psi - \theta)} \langle \sin \theta \cos \theta \rangle) Z, \tag{A8}$$

$$R_s = (J_0 R e^{-i(\theta_\psi - \theta)} \sin \theta) + J_1 (R_c e^{i(\theta_\psi - \theta)} \langle \sin \theta \cos \theta \times + R_s \langle \sin^2 \theta \rangle)) Z. \tag{A9}$$

The real parts of Eqs. (A7), (A8), and (A9) give the SCEs for $R, R_c$, and $R_s$:

$$R = (J_0 R + J_1 (R_c \cos \theta) \cos (\Theta - \Theta) \times + R_s \langle \sin \theta \cos (\Theta - \Theta) \rangle) Z, \tag{A10}$$

$$R_c = (J_0 R \cos \theta) \cos (\Theta - \Theta) + J_1 (R_c \cos^2 \theta) \times + R_s \langle \sin \theta \cos \theta \cos (\Theta - \Theta) \rangle) Z, \tag{A11}$$

$$R_s = (J_0 R \sin \theta) \cos (\Theta - \Theta) + J_1 (R_c \sin \theta \cos \theta) \times \cos (\Theta - \Theta) + R_s \langle \sin^2 \theta \rangle) Z. \tag{A12}$$

The imaginary parts of Eqs. (A7), (A8), and (A9) give three equations,

$$R_c \cos \theta \sin (\Theta - \Theta) + R_s \langle \sin \theta \rangle \sin (\Theta - \Theta) = 0, \tag{A13}$$

$$J_0 R \cos \theta \sin (\Theta - \Theta) \times + J_1 R_s \langle \sin \theta \cos \theta \rangle \sin (\Theta - \Theta) = 0, \tag{A14}$$

$$J_0 R \sin \theta \sin (\Theta - \Theta) \times - J_1 R_s \langle \sin \theta \cos \theta \rangle \sin (\Theta - \Theta) = 0. \tag{A15}$$

Two of Eqs. (A13), (A14), and (A15) are independent. These auxiliary equations completely determine the phases of the order parameters.
Now, let us solve the auxiliary equations. We will concentrate on the solutions that are relevant to the phase transitions. First, we solve the case of $R = 0$ and $R_1 = \sqrt{R_s^2 + R_c^2} \neq 0$ and derive the phases of the order parameters for the stable $S$ solution.

\textit{Case of $R = 0, R_1 \neq 0$.} Since $A_0$ does not have $\cos \theta$ and $\sin \theta$ terms, $\langle \cos \theta \rangle = \langle \sin \theta \rangle = 0$ follows. Thus, from Eqs. (A14) and (A15), we obtain 
\begin{align}
J_1 R_c \langle \sin \theta \cos \theta \rangle \sin(\Theta_c - \Theta_s) &= 0, \quad (A16) \\
J_1 R_c \langle \sin \theta \cos \theta \rangle \sin(\Theta_c - \Theta_s) &= 0. \quad (A17)
\end{align}

Therefore, we have 
\[ \langle \sin \theta \cos \theta \rangle \sin(\Theta_c - \Theta_s) = 0. \]

The case of $\langle \sin \theta \cos \theta \rangle \sin(\Theta_c - \Theta_s) = 0$ gives an irrelevant solution, so we will omit discussion of this case.

Now let us study the case $\langle \sin \theta \cos \theta \rangle = 0$. Here, the Fourier expansion of the integrand should not contain the Fourier component $\sin \theta \cos \theta$. Therefore, the coefficient of $\sin \theta \cos \theta$ in $A_0$ should be 0, that is, $R_c R_s \cos(\Theta_c - \Theta_s) = 0$. Thus, $\cos(\Theta_c - \Theta_s) = 0$, or $R_c = 0$, or $R_s = 0$. $R_c = 0$ or $R_s = 0$ gives irrelevant solutions, and the relevant solution is when $\cos(\Theta_c - \Theta_s) = 0$, that is, $\Theta_c - \Theta_s = \pm \frac{\pi}{2}$ (mod $2\pi$). Therefore, we omit “(mod $2\pi$)” for simplicity. Numerical results show that this case corresponds to the stable $S$ solution.

Next, we solve the case of $R \neq 0, R_1 \neq 0, R_s = 0$ and derive the phases of the order parameters for the $Pn$ solutions.

\textit{Case of $R \neq 0, R_1 \neq 0, R_s = 0$.} Using Eq. (A14) and $\Theta_c - \Theta = (\Theta_c - \Theta_s) - (\Theta_s - \Theta)$ and multiplying Eq. (A15) by $\langle \cos \theta \rangle$, we obtain 
\begin{align}
\sin(\Theta_c - \Theta_s) \{ J_1 R_c \langle \sin \theta \cos \theta \rangle \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta_s) \\
+ \langle \cos \theta \rangle \{ J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta) \\
+ J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta_s) \} = 0. \quad (A18)
\end{align}

\textit{Case 1} $\sin(\Theta_c - \Theta_s) = 0$, that is, $\Theta_c - \Theta_s = \{0, \pi\}$.

From Eq. (A14), we obtain 
\[ J_0 R_c \langle \cos \theta \rangle \sin(\Theta_c - \Theta) = 0. \]

Thus, $\Theta_c - \Theta = \{0, \pi\}$ or $\langle \cos \theta \rangle = 0$ follows. The relevant solution is obtained from the case $\langle \cos \theta \rangle = 0$. In this case, $A_0$ should not contain any $\cos \theta$ term, that is, $R_c \cos(\Theta_c - \Theta) \langle \sin \theta \cos \theta \rangle = 0$. Therefore, $\cos(\Theta_c - \Theta) = 0$, i.e., $\Theta_c - \Theta = \pm \frac{\pi}{2}$. Since $\Theta_s - \Theta = (\Theta_c - \Theta) - (\Theta_c - \Theta_s) = \pm \frac{\pi}{2}$, we obtain 
\[ \{ \Theta_c - \Theta, \Theta_s - \Theta \} = \{ \pm \frac{\pi}{2}, \pm \frac{\pi}{2} \}. \]

Numerical results show that this is the stable $Pn$ solution.

Using Eq. (A13) and $\Theta_c - \Theta_s = (\Theta_c - \Theta) - (\Theta_s - \Theta)$ and multiplying Eq. (A14) by $\langle \sin \theta \rangle$, we obtain 
\begin{align}
\sin(\Theta_c - \Theta) \{ J_1 R_c \langle \cos \theta \rangle \\
+ J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta) \\
+ J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta_s) \} &= 0. \quad (A19)
\end{align}

\textit{Case 2} $\sin(\Theta_c - \Theta) = 0$, that is, $\Theta_c - \Theta = \{0, \pi\}$.

From Eq. (A13), $R_c \langle \sin \theta \rangle \sin(\Theta_c - \Theta) = 0$. Thus, $\Theta_c - \Theta = \{0, \pi\}$, or $\langle \sin \theta \rangle = 0$. The relevant solution is obtained from $\langle \sin \theta \rangle = 0$. In this case, $R_c \cos(\Theta_s - \Theta) = 0$. Therefore, $\cos(\Theta_s - \Theta) = 0$, that is, $\Theta_s - \Theta = \pm \frac{\pi}{2}$. Thus, we obtain 
\[ \{ \Theta_c - \Theta, \Theta_s - \Theta \} = \{ 0, \pi, \pm \frac{\pi}{2} \}. \]

It turns out that this $Pn$ solution is unstable.

Using Eq. (A13) and $\Theta_c - \Theta_s = (\Theta_c - \Theta) - (\Theta_s - \Theta)$ and multiplying Eq. (A15) by $\langle \cos \theta \rangle$, we obtain 
\[ \sin(\Theta_c - \Theta) \{ \cos(\Theta_c - \Theta) \} J_0 R_c \langle \sin \theta \rangle \\
+ J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta) \\
+ J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta_s) \} = 0. \quad (A20) \]

\textit{Case 3} $\sin(\Theta_c - \Theta) = 0$, that is, $\Theta_s - \Theta = \{0, \pi\}$.

In this case, from Eq. (A13), we have 
\[ R_c \langle \cos \theta \rangle \sin(\Theta_c - \Theta) = 0. \]

It follows that $\Theta_c - \Theta = \{0, \pi\}$, or $\langle \cos \theta \rangle = 0$.

\textit{Case 3-1} $\sin(\Theta_c - \Theta) = 0$.

Moreover, it follows that $\{ \Theta_c - \Theta, \Theta_s - \Theta \} = \{0, \pi, 0, \pi\}$. These solutions are unstable and irrelevant.

\textit{Case 3-2} $\langle \cos \theta \rangle = 0$.

In this case, $R_c \cos(\Theta_c - \Theta) = 0$. Thus, $\cos(\Theta_s - \Theta) = 0$, and $\Theta_c - \Theta = \pm \frac{\pi}{2}$. Therefore, we have $\{ \Theta_c - \Theta, \Theta_s - \Theta \} = \{ \pm \frac{\pi}{2}, 0, \pi \}$. These solutions are unstable.

\textit{Other cases}.

The other conditions for (A18), (A19), and (A20) are 
\begin{align}
J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta_s) \\
+ (\cos \theta) \{ J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta) \\
+ J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta_s) \} &= 0, \quad (A21) \\
\langle \sin \theta \rangle \{ J_0 R_c \langle \cos \theta \rangle + J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_s - \Theta) \} \\
+ J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta_s) &= 0, \quad (A22) \\
\langle \cos \theta \rangle \{ J_0 R_c \langle \sin \theta \rangle + J_1 R_c \langle \sin \theta \cos \theta \rangle \cos(\Theta_c - \Theta) \} \\
+ J_1 R_c \langle \sin \theta \cos \theta \rangle \langle \sin \theta \rangle \cos(\Theta_s - \Theta) &= 0. \quad (A23)
\end{align}

Since $R_c, R_1$, and $R_s$ are continuous functions with respect to the parameters $J_0$ and $J_1$, the conditions under which the above equalities hold are that the coefficients of $R_c R_1$ are 0. The conditions for $\langle \cos \theta \rangle = 0$ and for $\cos(\Theta_s - \Theta) = 0$ are the same, and $\Theta_s - \Theta = \pm \frac{\pi}{2}$. Similarly, the condition for $\langle \sin \theta \rangle = 0$ and for $\cos(\Theta_s - \Theta) = 0$ is $\Theta_s - \Theta = \pm \frac{\pi}{2}$, and the condition for $\langle \sin \theta \rangle = 0$ and for $\cos(\Theta_s - \Theta) = 0$ is $\Theta_c - \Theta = \pm \frac{\pi}{2}$. The combination of phases of the order parameters is the same as that in cases 1 to 3.

\begin{center}
\textbf{APPENDIX B: DERIVATION OF CONCRETE SCEs AND RELEVANT QUANTITIES FOR EACH PHASE}
\end{center}

\section{1. Stable uniform solution}

This is the case of $R > 0$ and $R_1 = 0$. This is merely the solution of the Kuramoto model. Since $R_1 = 0$, we have 
\[ A_0 e^{i\phi} = J_0 R e^{i\phi}, \quad \phi = J_0 R, \quad \phi = \phi' = \text{const}. \]
Therefore, the entrained phase $\phi_0^*$ is expressed as
\[
\phi_0^* = \omega_0 t + \Theta^* + \sin^{-1}\left(\frac{\omega_0 - \omega_0}{J_0 R}\right).
\]
Note that $\Theta^* = \Theta - \omega_0 t$ is used in the expressions of $\alpha_0$ ad $\phi_0^*$. The SCE is
\[
R = 2J_0 R \int_0^{\pi/2} d\psi \, g(\omega_0 + J_0 R \sin \psi) \cos^2 \psi. \quad (B1)
\]
The phase transition point from the $P$ phase to the $U$ phase is
\[
J_{0,c} = \frac{2}{\pi g(\omega_0)}, \quad (B2)
\]
2. Stable $S$ solution
For the stable $S$ solution, $R = 0$, $\langle \cos \theta \rangle = \langle \sin \theta \rangle = 0$, and $\Theta_c - \Theta_s = \frac{\pi}{2}$ (see Appendix A). In this case, $A_0$ is expressed as $A_0 = J_1 \sqrt{(R_c \cos \theta)^2 + (R_s \sin \theta)^2}$. From Eqs. (A11) and (A12), we have
\[
R_c = J_1 R_c (\cos^2 \theta) Z, \quad R_s = J_1 R_s (\sin^2 \theta) Z.
\]
If $R_c, R_s \neq 0$, then $\langle \cos^2 \theta \rangle = \langle \sin^2 \theta \rangle$ holds. $R_c = R_s = \frac{B_0}{\pi}$ follows from this. Accordingly, $A_0 = J_1 R_c$, and the SCE becomes
\[
R_c = J_1 R_c \int_0^{\pi/2} d\psi \, g(\omega_0 + J_1 R_c \sin \psi) \cos^2 \psi. \quad (B3)
\]
The phase transition point from the $P$ phase to the $S$ phase and the order parameter $R_1$ near to the transition point are given by
\[
J_{1,c} = \frac{4}{\pi g(\omega_0)^2} = 2J_{0,c},
\]
\[
R_1 \simeq \frac{4}{J_{1,c}} \sqrt{\frac{2(J_1 - J_{1,c})}{\pi |g'(\omega_0)|}} \propto \sqrt{J_1 - J_{1,c}}. \quad (B4)
\]
When $g(\omega)$ is a Gaussian distribution with mean $\omega_0$ and standard deviation $\sigma$, $J_{0,c}$ and $J_{1,c}$ are given by
\[
J_{0,c} = 2\sqrt{\frac{2}{\pi}} \sigma, \quad J_{1,c} = 4\sqrt{\frac{2}{\pi}} \sigma = 2J_{0,c}. \quad (B4)
\]
Let us study the entrained phase $\phi_0^*$ = $\omega_0 t + \psi_0^* + \alpha_0$. Since $\Theta_c - \Theta_s = \frac{\pm \pi}{2}$, $\Theta_c = \Theta_s - (\Theta_c - \Theta_s) = \Theta_s + \frac{\pi}{2}$. From Eq. (8), we have
\[
A_0 e^{i\phi_0^*} = J_1 R_c e^{i(\cos \theta + \sin \theta e^{i\pi/2})} = J_1 R_c e^{i(\Theta_0^*, \Theta)}.
\]
Therefore, $A_0 = J_1 R_c$ and $\alpha_0 = \Theta^* \neq \Theta$. Accordingly, the entrained phase $\phi_0^*$ is
\[
\phi_0^* = \omega_0 t + \psi_0^* + \alpha_0 = \omega_0 t + \sin^{-1}\left(\frac{\omega_0 - \omega_0}{J_1 R_c}\right) + \Theta_c^* \neq \Theta. \quad (B5)
\]
Thus, the entrained phase $\phi_0^*$ linearly depends on the location $\theta$.

3. Stable $Pn$ solution
Since $\{\Theta_c - \Theta_s, \Theta_s - \Theta\} = \{0, \frac{\pi}{2}\}$, by using $\sin(\Theta_c - \Theta) = \pm 1$, $\cos(\Theta_c - \Theta) = \pm 1$, and $\sin(\Theta_c - \Theta_s) = \pm 1$, $\cos(\Theta_c - \Theta_s) = 0$, Eq. (8) reduces to
\[
A_0 e^{i\phi_0^*} = J_0 R_c e^{i(\Theta_c^*, \Theta)} + J_1 R_c \cos \theta,
\]
\[
- i J_1 R_c \sin \theta \sin(\Theta_c - \Theta_s).
\]
Therefore, setting $\alpha_0 = \Theta_c - \Theta_s$, we have
\[
A_0 \sin \alpha_0 = -J_0 R_c \sin(\Theta_c - \Theta), \quad (B6)
\]
\[
A_0 \cos \alpha_0 = J_1 R_c \cos \Theta - \psi \cos(\Theta_c - \Theta_s) \cos \theta, \quad (B7)
\]
Equations (A10), (A11), and (A12) become
\[
R = J_0 R Z, \quad (B9)
\]
\[
R_c = J_1 R_c Z \cos^2 \theta - \varphi \cos(\Theta_c - \Theta_s) \sin \varphi, \quad (B10)
\]
\[
R_s = J_1 R_s Z \cos^2 \theta - \varphi \cos(\Theta_c - \Theta_s) \sin \varphi. \quad (B11)
\]
By transforming $\theta$ into $\theta' = \theta - \varphi \cos(\Theta_c - \Theta_s)$ and since $A_0^{\theta', \varphi \cos(\Theta_c - \Theta_s)}$ is periodic with period $\pi$ and an even function of $\theta'$, we obtain the following SCES:
\[
R = \frac{4J_0 R}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi/2} d\theta' \times g(\omega_0 + A_0^{\theta', \varphi \cos(\Theta_c - \Theta_s)} \sin \psi) \cos^2 \psi, \quad (B12)
\]
\[
R_1 = \frac{4J_1 R_1}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi/2} d\theta' \times g(\omega_0 + A_0^{\theta', \varphi \cos(\Theta_c - \Theta_s)} \sin \psi) \cos^2 \psi \cos^2 \theta', \quad (B13)
\]
\[
A_0^{\theta', \varphi \cos(\Theta_c - \Theta_s)} = \sqrt{(J_0 R)^2 + (J_1 R_1)^2 \cos^2 \theta'}. \quad (B14)
\]
In this solution, we have
\[
\phi_0^* = \omega_0 t + \alpha_0 + \sin^{-1}\left(\frac{\omega_0 - \omega_0}{A_0}\right) = \omega_0 t + \alpha_0 + \Theta_c^* \neq \Theta. \quad (B5)
\]
\[
+ \sin^{-1}\left(\frac{\omega_0 - \omega_0}{A_0}\right), \quad (B15)
\]
where $\theta$ is the original coordinate and $A_0$ is given by Eq. (B8).

4. Unstable $Pn$ solution
Since $\{\Theta_c - \Theta_s, \Theta_s - \Theta\} = \{0, \frac{\pi}{2}\}$, then $\sin(\Theta_c - \Theta) = 0$, $\cos(\Theta_c - \Theta) = \pm 1$, $\sin(\Theta_c - \Theta) = \pm 1$, $\cos(\Theta_c - \Theta) = 0$, $\sin(\Theta_c - \Theta_s) = \pm 1$, and $\cos(\Theta_c - \Theta_s) = 0$. Equation (8) reduces to
\[
A_0 e^{i\phi_0^*} = e^{i\Theta_c} [J_0 R_c e^{-i(\Theta_c^*, \Theta)}] + J_1 R_c \cos \theta,
\]
\[
- i J_1 R_c \sin \theta \sin(\Theta_c - \Theta_s).\]

032918-14
Therefore, setting $\tilde{a}_\theta = \alpha_\theta - \Theta_c$, we have
\[
A_\theta \sin \tilde{a}_\theta = -J_1 R_c \sin \theta \sin(\Theta_c - \theta), \quad A_\theta \cos \tilde{a}_\theta = J_0 R \cos(\Theta_c - \theta) + J_1 R_c \cos \theta, \quad A_\theta = \sqrt{[J_0 R \cos(\Theta_c - \theta) + J_1 R_c \cos \theta]^2 + (J_1 R_c \sin \theta)^2}.
\]

Accordingly, Eqs. (A10), (A11), and (A12) become
\[
R = \langle J_0 R + J_1 R_c \cos(\theta - (\Theta_c - \Theta)) \rangle Z, \quad (B17)
\]
\[
R_c = \langle [J_0 R + J_1 R_c \cos(\theta - (\Theta_c - \Theta))] \times \cos(\theta - (\Theta_c - \Theta)) \rangle Z, \quad (B18)
\]
\[
R_x = \langle J_1 R_c \sin^2(\theta - (\Theta_c - \Theta)) \rangle Z. \quad (B19)
\]

By transforming $\theta$ into $\theta' = \theta - (\Theta_c - \Theta)$ and since $A_{\theta'+\Theta_c-\Theta}$ is periodic with period $\pi$ and an even function of $\theta'$, Eqs. (B17), (B18), and (B19) can be expressed as
\[
R = \frac{2}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi} d\theta' g(\omega_0 + A_{\theta'+\Theta_c-\Theta} \sin \psi) \cos^2 \psi (J_0 R + J_1 R_c \cos \theta'), \quad (B20)
\]
\[
R_c = \frac{2}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi} d\theta' g(\omega_0 + A_{\theta'+\Theta_c-\Theta} \sin \psi) \times \cos^2 \psi (J_0 R + J_1 R_c \cos \theta') \cos \theta', \quad (B21)
\]
\[
R_x = J_1 R_c \frac{2}{\pi} \int_0^{\pi/2} d\psi \int_0^{\pi} d\theta' g(\omega_0 + A_{\theta'+\Theta_c-\Theta} \sin \psi) \cos^2 \psi \sin \theta', \quad (B22)
\]

where $A_{\theta'+\Theta_c-\Theta} = \sqrt{(J_0 R + J_1 R_c \cos \theta')^2 + (J_1 R_c \sin \theta')^2}$.

APPENDIX C: CONDITION ON THE EXISTENCE OF THE $P_n$ SOLUTION, $J_1 > 2J_0$

Let us consider a bifurcation from a solution with $R > 0$ and $R_1 = 0$ to a solution with $R > 0$ and $R_1 > 0$. Let us define $X(R)$ and $Y(R)$ as follows:
\[
X(R) \equiv \frac{2}{\pi} \int_0^{\pi/2} d\psi g(\omega_0 + J_0 R \sin \psi) \cos^2 \psi, \quad (C1)
\]
\[
Y(R) \equiv -\frac{2}{\pi} \int_0^{\pi/2} d\psi g'(\omega_0 + J_0 R \sin \psi) \sin \psi \cos^2 \psi. \quad (C2)
\]

$X(R) > 0$ follows from Eq. (C1), since we assumed $R > 0$. Integrating the right-hand side of Eq. (C2) by parts yields
\[
Y(R) = -\frac{2J_0 R}{3\pi} \int_0^{\pi/2} d\psi g''(\omega_0 + J_0 R \sin \psi) \cos^4 \psi. \quad (C3)
\]

Here, we assume that $g''(x)$ exists. Note that $g'(\omega_0) = 0$ by definition. Since $\omega_0$ is the unique maximum of $g(\omega), g''(\omega) \leq 0$ follows. Thus, $Y(R) > 0$ since $R > 0$. Defining $\varepsilon \equiv \frac{J_0 R}{3R} \frac{\pi}{\sqrt{2}}$ for $\varepsilon \ll 1$, from Eqs. (B12) and (B13), we obtain
\[
R \simeq 2J_0 R \left\{ \frac{\pi}{2} - \frac{\pi}{8} J_0 R e^2 Y \right\}, \quad (C4)
\]
\[
R_1 \simeq 2J_1 R_1 \left\{ \frac{\pi}{4} - \frac{3\pi}{16} J_0 R e^2 Y \right\}. \quad (C5)
\]

When $\varepsilon = 0$, $R_1 = 0$. Let us set $R = R^*$ at $\varepsilon = 0$. Then, from Eq. (C4), we obtain
\[
1 = \pi J_0 X(R^*). \quad (C6)
\]

Thus, $R^*$ satisfies Eq. (B1) for the $U$ solution. Furthermore, from Eq. (C5), we obtain
\[
R_1 \simeq 2 \sqrt{\frac{R^*(J_1 - 2J_0)}{3\pi J_1 Y(R^*)}}. \quad (C7)
\]

Since $Y(R^*) > 0$, we find that the $P_n$ solution bifurcates from the $U$ solution at $J_1 = 2J_0$ and exists when $J_1 > 2J_0$.

APPENDIX D: DERIVATIONS OF THE PHASE BOUNDARIES

1. Boundaries between the $S$ and $U$ phases

We will analyze the SCES for the unstable $P_n$ solutions (B20), (B21), and (B22) and derive the boundary between the $S$ and $U$ phases. Assuming $R \ll 1$, we can expand $A_{\theta'+\Theta_c-\Theta}$ into a Taylor series up to $O(R)$,
\[
J_1 \tilde{A}(\theta') \equiv A_{\theta'+\Theta_c-\Theta} \simeq J_1 \tilde{A}_0(\theta') + \frac{J_0 R_c \cos \theta'}{\tilde{A}_0(\theta')} R,
\]
\[
\tilde{A}_0(\theta') = \sqrt{(R_c \cos \theta')^2 + (R_s \sin \theta')^2}.
\]

Thus, we obtain
\[
g(\omega_0 + J_1 \tilde{A}(\theta') \sin \psi) \simeq g(\omega_0 + J_1 \tilde{A}_0(\theta') \sin \psi) + g'(\omega_0 + J_1 \tilde{A}_0(\theta') \sin \psi) \times \frac{J_0 R_c \cos \theta'}{\tilde{A}_0(\theta')} R \sin \psi.
\]

The SCES become
\[
R \simeq J_0 R Z_0 + J_1 R_c \langle \cos \theta' \rangle Z, \quad (D1)
\]
\[
R_c \simeq J_0 R \langle \cos \theta' \rangle Z_0 + J_1 R_c \langle \cos^2 \theta' \rangle Z, \quad (D2)
\]
\[
R_x \simeq J_1 R_c \langle \sin^2 \theta' \rangle Z, \quad (D3)
\]
\[
\langle B \rangle_0 \equiv \frac{1}{Z_0} \int_0^{\pi/2} d\psi e^{i\theta} g(\omega_0 + J_1 \tilde{A}_0(\theta') \sin \psi) B. \quad (D4)
\]
\[ Z_0 = \frac{2}{\pi} \int_0^{\pi/2} d\psi \cos^2 \psi \]
\[ \times \int_0^{\pi} d\theta' g[\omega_0 + J_0 A_0(\theta') \sin \psi]. \quad (D5) \]

\( (\cos \theta_0) = 0 \) holds, and by setting \( R = 0 \), Eqs. (D2) and (D3) lead us to \( (\cos \theta_0) = (\sin^2 \theta_0) \). Thus, \( R_c = R_c \) is satisfied on the boundary. Therefore, we have
\[ A_0(\theta') = R_c = \frac{R_1}{\sqrt{2}}, \]
\[ \tilde{A}(\theta') \simeq J_1 R_c + J_1 R \cos \theta', \]
\[ (B)_0 = \frac{1}{Z_0} \int_0^{\pi/2} d\psi \cos^2 \psi \int_0^{\pi} d\theta' B, \]
\[ Z_0 = 2 \int_0^{\pi/2} d\psi \cos^2 \psi g(\omega_0 + J_1 R_c \sin \psi). \]

Thus, we obtain
\[ \langle \cos \theta' \rangle \simeq \frac{1}{Z} \int_0^{\pi/2} d\psi \cos^2 \psi g(\omega_0 + J_1 R_c \sin \psi) \int_0^{\pi} d\theta' (g(\omega_0 + J_1 R_c \sin \psi) + \hat{g}(\omega_0 + J_1 R_c \sin \psi) \cos \theta')\]
\[ + g'_{\omega_0 + J_1 R_c \sin \psi} J_1 R_c \sin \psi). \quad (D6) \]

Thus, on the boundary, we have
\[ 1 = 2 J_0 \int_0^{\pi/2} d\psi \cos^2 \psi g(\omega_0 + J_1 R_c \sin \psi) + J_0 J_1 R_c \]
\[ \times \int_0^{\pi/2} d\psi \cos^2 \psi g'(\omega_0 + J_1 R_c \sin \psi) \sin \psi. \quad (D7) \]

On the other hand, on the boundary, Eq. (D2) becomes
\[ R_c = J_1 R_c \cos^2 \theta' = \frac{1}{Z_0} Z_0 \]
\[ = J_1 R_c \int_0^{\pi/2} d\psi \cos^2 \psi g(\omega_0 + J_1 R_c \sin \psi). \quad (D8) \]

This is nothing but the SCE (B3) for the stable \( S \) solution. Therefore, Eq. (D7) becomes
\[ \frac{1}{2} = 2 J_0 J_1 R_c \int_0^{\pi/2} d\psi \cos^2 \psi \]
\[ \times g'(\omega_0 + J_1 R_c \sin \psi) \sin \psi. \quad (D9) \]

This can be rewritten as
\[ J_0 = \left[ \frac{2}{J_1} + J_0 J_1 R_c \int_0^{\pi/2} d\psi \right]^{-1}, \quad (D10) \]

which is the formula of the boundary between the \( S \) and \( U \) phases. We define \( \hat{g}(x) = \sigma^2 g(\omega_0 + \sigma x) \), and consequently \( \hat{g}'(x) = \sigma^2 g'(\omega_0 + \sigma x) \) follows. Defining \( \tilde{J}_1 = \frac{J_1}{\sigma} \), we can rewrite Eqs. (D8) and (D10) as
\[ R_c = \tilde{J}_1 R_c \int_0^{\pi/2} d\psi \cos^2 \psi \hat{g}(\tilde{J}_1 R_c \sin \psi), \quad (D11) \]
\[ \tilde{J}_0 = \left[ \frac{2}{\tilde{J}_1} + \tilde{J}_0 \tilde{J}_1 R_c \sin \psi \right]^{-1}. \quad (D12) \]

If \( g(\omega) \) is a Gaussian distribution with mean \( \omega_0 \) and standard deviation \( \sigma \), we have
\[ \hat{g}(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}, \quad \hat{g}'(x) = -x \frac{1}{\sqrt{2\pi}} e^{-x^2/2}. \]

2. Boundary between \( S \) and \( Pn \) phases

The boundary between \( S \) and \( Pn \) phases is obtained from the SCEs for the unstable \( Pn \) solution by setting \( R_c = 0 \). Assuming \( R_c \ll 1 \), we can expand \( \tilde{A}(\theta') \) into a Taylor series up to \( O(R_c) \). Defining \( \tilde{A}(\theta') = \tilde{A}(\theta')/\sigma \), we obtain
\[ \tilde{A}(\theta') = \sqrt{(\tilde{J}_0 R + \tilde{J}_1 R_c \cos \theta')^2 + (\tilde{J}_1 R_c \sin \theta')} \]
\[ \simeq \tilde{A}_0(\theta') + \tilde{J}_0 \tilde{J}_1 R_c \cos \theta' \frac{(\tilde{J}_0 R + \tilde{J}_1 R_c \cos \theta')^2}{\tilde{A}_0(\theta')}, \]
\[ \tilde{A}_0(\theta') = \sqrt{(\tilde{J}_0 R_c)^2 + (\tilde{J}_1 R_c \sin \theta')}^2. \]

Accordingly, we have
\[ g[\omega_0 + J_1 \tilde{A}_0(\theta') \sin \psi] \simeq g[\omega_0 + \sigma \tilde{A}_0(\theta') \sin \psi] \]
\[ + g'[\omega_0 + \sigma \tilde{A}_0(\theta') \sin \psi] \]
\[ \times \tilde{J}_0 \tilde{J}_1 R_c \cos \theta' \frac{(\tilde{J}_0 R + \tilde{J}_1 R_c \cos \theta')^2}{\tilde{A}_0(\theta')} \sin \psi. \]

The SCE (B21) for \( R_c \) becomes
\[ R_c \simeq \frac{2}{\pi} \int_0^{\pi/2} d\psi \cos^2 \psi \int_0^{\pi} d\theta' \hat{g} \tilde{A}_0(\theta') \sin \psi \]
\[ + \hat{g}' \tilde{A}_0(\theta') \sin \psi \frac{(\tilde{J}_0 R + \tilde{J}_1 R_c \cos \theta')^2}{\tilde{A}_0(\theta')} \sin \psi \]
\[ \times \tilde{J}_0 \tilde{J}_1 R_c \cos \theta' \frac{(\tilde{J}_0 R + \tilde{J}_1 R_c \cos \theta')^2}{\tilde{A}_0(\theta')} \sin \psi. \quad (D13) \]

Thus, the boundary between the \( S \) and \( Pn \) phases is given by
\[ 1 = \frac{2}{\pi} \tilde{J}_1 \int_0^{\pi/2} d\psi \cos^2 \psi \int_0^{\pi} d\theta' \hat{g} \tilde{A}_0(\theta') \sin \psi \]
\[ + \hat{g}' \tilde{A}_0(\theta') \sin \psi \frac{(\tilde{J}_0 R + \tilde{J}_1 R_c \cos \theta')^2}{\tilde{A}_0(\theta')} \sin \psi \]
\[ \times \tilde{J}_0 \tilde{J}_1 R_c \cos \theta' \frac{(\tilde{J}_0 R + \tilde{J}_1 R_c \cos \theta')^2}{\tilde{A}_0(\theta')} \sin \psi. \quad (D14) \]

On the other hand, on the boundary, the SCEs (B20) and (B22) for \( R \) and \( R_c \) become
\[ R = \sigma \tilde{J}_0 R \frac{2}{\pi} \int_0^{\pi/2} d\psi \cos^2 \psi \int_0^{\pi} d\theta' g[\omega_0 + \sigma \tilde{A}_0(\theta') \sin \psi], \quad (D15) \]
\[ R_c = \sigma \tilde{J}_1 R_c \frac{2}{\pi} \int_0^{\pi/2} d\psi \cos^2 \psi \]
\[ \times \int_0^{\pi} d\theta' g[\omega_0 + \sigma \tilde{A}_0(\theta') \sin \psi] \sin^2 \theta'. \quad (D16) \]
Since $R_c = 0$ on the boundary, $R_1 = R_2$ holds. Furthermore, since the integrand is symmetric with respect to $\theta' = \frac{\pi}{2}$, changing the integral range from $[0, \pi]$ to $[0, \frac{\pi}{2}]$ and making a variable transformation $\theta' \rightarrow \frac{\pi}{2} - \theta''$ yields

$$R = \sigma J_0 R \frac{4}{\pi} \int_0^{\pi/2} d\psi \cos^2 \psi \left[ \int_0^{\pi/2} d\theta'' g[\omega_0 + \sigma \tilde{A}_0(\theta'') \sin \psi] \right].$$

(E17)

$$R_1 = \sigma J_1 R_1 \frac{4}{\pi} \int_0^{\pi/2} d\psi \cos^2 \psi \left[ \int_0^{\pi/2} d\theta'' g[\omega_0 + \sigma \tilde{A}_0(\theta'') \sin \psi] \right].$$

(E18)

These are merely the SCEs (B12), (B13), and (B14) for the stable $Pn$ solution. Now, let us summarize the formulas of the boundary between the $S$ and $Pn$ solutions,

$$\tilde{J}_1 = \left[ \frac{4}{\pi} \int_0^{\pi/2} d\psi \cos^2 \psi \left[ \int_0^{\pi/2} d\theta'' g[\tilde{A}_0(\theta'') \sin \psi] \right] + g'[\tilde{A}_0(\theta'') \sin \psi] \left( \frac{J_0 R}{\tilde{A}_0(\theta'')} \sin \psi \right) \sin^2 \theta'' \right]^{-1},$$

(E20)

$$R = \tilde{J}_0 R \frac{4}{\pi} \int_0^{\pi/2} d\psi \cos^2 \psi \left[ \int_0^{\pi/2} d\theta'' g[\tilde{A}_0(\theta'') \sin \psi] \right].$$

(E21)

$$R_1 = \tilde{J}_1 R_1 \frac{4}{\pi} \int_0^{\pi/2} d\psi \cos^2 \psi \left[ \int_0^{\pi/2} d\theta'' g[\tilde{A}_0(\theta'') \sin \psi] \right].$$

(E22)

$$\tilde{A}_0(\theta'') = \sqrt{(\tilde{J}_0 R)^2 + (\tilde{J}_1 R_1 \cos \theta'')^2}.$$

(D23)

**APPENDIX E: DERIVATION OF THE SCEs FOR THE SPINNING SOLUTION AND PENDULUM SOLUTION FOR MODEL 2**

In model 2, the interaction is given by

$$J_{\theta', \delta} = \frac{1}{N} \left( J_m \cos[m(\theta - \theta')] + J_n \cos[n(\theta - \theta')] \right).$$

(E1)

where $m$ and $n$ are positive integers, and we assume $m < n$. Order parameters are defined as

$$R_{kc} e^{i\phi_{kc}} = \frac{1}{N} \sum_{\theta} \cos(k\theta) e^{i\phi_{kc}},$$

(E2)

$$R_{ks} e^{i\phi_{ks}} = \frac{1}{N} \sum_{\theta} \sin(k\theta) e^{i\phi_{ks}}.$$  

(E3)

$k$ is $m$ or $n$. As usual, we assume that $R_{kc}$ and $R_{ks}$ tend to be constant and $\Theta_{kc} \rightarrow \omega_{0}t + \Theta'_{kc}$, $\Theta_{ks} \rightarrow \omega_{0}t + \Theta'_{ks}$ as $t$ tends to $\infty$, and $\Theta_{kc}'$ and $\Theta_{ks}'$ are constant. The evolution equation for $\phi_0$ reduces to

$$\frac{d}{dt} \phi_0 = \omega_0 - A_{\delta} \sin(\delta - \phi_0 - \omega_0 t - \phi_0),$$

$$A_{\delta} e^{i\omega_0} = \sum_{k=m,n} J_k \left[ R_{kc} \cos(k\theta) e^{i\Theta_{kc}} + R_{ks} \sin(k\theta) e^{i\Theta_{ks}} \right].$$

(E4)

Defining $\psi_0 = \phi_0 - \omega_0 t - \phi_0$, the evolution equation becomes

$$\frac{d}{dt} \psi_0 = \omega_0 - \omega_0 - A_{\delta} \sin \psi_0.$$  

(E5)

The order parameters are calculated as follows:

$$R_{kc} = \frac{1}{2\pi} \int_0^{2\pi} d\theta' \int_0^{\pi/2} d\psi \sin(\phi_0(t, \psi)) \cos(k\theta) e^{i(\psi_0 + \omega_0 t - \Theta_{kc})},$$

(E6)

$$R_{ks} = \frac{1}{2\pi} \int_0^{2\pi} d\theta' \int_0^{\pi/2} d\psi \sin(\phi_0(t, \psi)) \sin(k\theta) e^{i(\psi_0 + \omega_0 t - \Theta_{ks})}.$$  

(E7)

From these equations, we obtain

$$R_{kc} = Z \sum_{k=m,n} J_k \left[ R_{kc} \cos(k\theta) \cos(k\theta) e^{i(\Theta_{kc} - \Theta_{kc})} + R_{ks} \sin(k\theta) \cos(k\theta) e^{i(\Theta_{kc} - \Theta_{ks})} \right],$$

(E8)

$$R_{ks} = Z \sum_{k=m,n} J_k \left[ R_{kc} \cos(k\theta) \sin(k\theta) e^{i(\Theta_{kc} - \Theta_{kc})} + R_{ks} \sin(k\theta) \sin(k\theta) e^{i(\Theta_{kc} - \Theta_{ks})} \right].$$

(E9)

$Z$ and $\langle \rangle$ mean the same as before. That is,

$$\langle B \rangle = \frac{1}{Z} \int \frac{1}{2\pi} \int_0^{\pi/2} d\psi \sin(\omega_0 + A_{\delta}) \cos^2 \psi B,$$

(E10)

$$Z = \frac{1}{2\pi} \int_0^{2\pi} d\theta' \int_0^{\pi/2} d\psi \sin(\omega_0 + A_{\delta}) \cos^2 \psi.$$  

(E11)

We further define $R_k$ and $\phi_k$ by $R_k + i R_k' = R_k e^{i\phi_k}$. For simplicity, we omit primes from the $\Theta$’s except for the expressions of $\alpha_0$ and $\phi_0$.

**1. Spinning solution**

First, let us study the spinning solution. We will assume $R_m > 0, R_n = 0$ and examine the auxiliary equations, which are the imaginary parts of Eqs. (E8) and (E9),

$$R_m \sin(m \varphi_m) \cos(m \theta) \sin(m \varphi_m) \sin(\Theta_{mc} - \Theta_{mc}) = 0,$$

(E12)

$$R_m \cos(m \varphi_m) \cos(m \theta) \sin(m \varphi_m) \sin(\Theta_{mc} - \Theta_{mc}) = 0.$$  

(E13)

These equations are similar to Eqs. (A16) and (A17) in Appendix A. Therefore, for the stable $S$ solution, $\cos(\Theta_{mc} - \Theta_{mc}) = 0$ and $\cos(m \varphi_m) \sin(m \varphi_m) = 0$ follow, and
The sufficient conditions for these equations are that the coefficients of $R_m$ ad $R_s$ are 0. Accordingly, we obtain
\[
\sin(m \psi_m)(\cos(m \theta) \sin(m \theta)) \sin(\Theta_{mc} - \Theta_{ms}) = 0, \tag{E26}
\]
\[
J_n R_s \sin(n \psi_s)(\cos(n \theta) \sin(n \theta)) \sin(\Theta_{nc} - \Theta_{ns}) = 0. \tag{E27}
\]
For the pendulum solution, we assume $\sin(\Theta_{mc} - \Theta_{ms}) = 0$ and $\sin(\Theta_{nc} - \Theta_{ns}) = 0$ because similar conditions are obtained in model 1 for the stable $P$ solution.

The imaginary part of Eq. (E8) with $k = m + i \times$ the imaginary part of Eq. (E9) with $k = m$, and [the imaginary part of Eq. (E8) with $k = n + i \times$ the imaginary part of Eq. (E9) with $k = n$] reduce to
\[
\sin(\Theta_{nc} - \Theta_{ns}) (e^{i m \phi} \cos(\Theta_{mc} - \Theta_{ms}) \cos(n \theta - \tilde{\theta})) = 0, \tag{E28}
\]
\[
\sin(\Theta_{nc} - \Theta_{ns}) (e^{i n \phi} \cos(\Theta_{nc} - \Theta_{ns}) \cos(m \theta')) = 0. \tag{E29}
\]
Here, we define
\[
\tilde{\theta}_k = \psi_k e^{i (\Theta_{kc} - \Theta_{kc})} = \psi_k (\Theta_{kc} - \Theta_{kc}),
\]
\[
\tilde{\theta} = \tilde{\theta}_n - \tilde{\theta}_m, \quad \theta' = \theta - \tilde{\theta}_m.
\]
We assume that $\sin(\Theta_{nc} - \Theta_{ns}) \neq 0$. From the real and imaginary parts of Eq. (E28), we obtain
\[
\langle \cos(m \theta) \cos(n \theta' - \tilde{\theta}) \rangle = 0, \tag{E30}
\]
\[
\langle \sin(m \theta) \cos(n \theta' - \tilde{\theta}) \rangle = 0. \tag{E31}
\]
From the real and imaginary parts of Eq. (E29), we obtain
\[
\langle \cos(n \theta) \cos(m \theta') \rangle = 0, \tag{E32}
\]
\[
\langle \sin(n \theta) \cos(m \theta') \rangle = 0. \tag{E33}
\]
[Equation (E30) + $i \times$ Eq. (E31)] and [Eq. (E32) + $i \times$ Eq. (E33)] reduce to
\[
\langle e^{i m \phi} \cos(n \theta' - \tilde{\theta}) \rangle = 0, \tag{E34}
\]
\[
\langle e^{i n \phi} \cos(m \theta') \rangle = 0, \tag{E35}
\]
where $\theta$ has been replaced with $\theta' + \tilde{\theta}_m$. From Eq. (E35), we obtain
\[
\langle \cos((m + n) \theta') \rangle + \langle \cos((n - m) \theta') \rangle = 0, \tag{E36}
\]
\[
\langle \sin((m + n) \theta') \rangle + \langle \sin((n - m) \theta') \rangle = 0. \tag{E37}
\]
On the other hand, by using Eq. (E35), Eq. (E34) reduces to
\[
\langle \sin((n - m) \theta' - n \tilde{\theta}) \rangle = 0. \tag{E38}
\]
$A_\theta = A_{\theta + \tilde{\theta}}$ is expressed as
\[
A_{\theta + \tilde{\theta}} = (J_m R_m)^2 \cos^2(m \theta') + (J_n R_s)^2 \cos^2(n \theta' - \tilde{\theta})
+ J_n J_m R_m R_s \cos(\Theta_{nc} - \Theta_{ns}) \cos(\Theta_{mc} - \Theta_{ms})
\times [\cos(n \theta')\cos((m + n) \theta' + \cos((n - m) \theta')]
+ \sin(n \theta')\sin((m + n) \theta') + \sin((n - m) \theta') \right)^{1/2}. \tag{E39}
\]
\[
\cos(\Theta_{nc} - \Theta_{ms}) \cos(n \tilde{\theta}) = 0 \text{ and } \cos(\Theta_{nc} - \Theta_{ns}) \sin(n \tilde{\theta}) = 0
\]
follow from Eqs. (E36) and (E37). That is,
\[
\cos(\Theta_{nc} - \Theta_{ms}) = 0. \tag{E40}
\]
Therefore, we obtain
\[ A_{\theta + \delta_n} = \sqrt{[J_m R_m \cos(m \theta')]^2 + [J_n R_n \cos(n(\theta' - \delta))]^2}. \] (E41)

Equation (E48) is automatically satisfied since \( \tilde{A}_\theta \) does not contain the factor \( \sin(2m \theta') \). From Eq. (E50), we have
\[ \langle \sin(2m \theta') \rangle \cos(2n \tilde{\theta}) = \langle \cos(2n \theta') \rangle \sin(2n \tilde{\theta}). \] (E51)

The sufficient condition for this is \( \cos(2n \tilde{\theta}) = 0 \) or \( \sin(2n \tilde{\theta}) = 0 \), and it determines the value of \( \tilde{\theta} \).

Therefore, the SPEs are
\[ 1 = J_m \tilde{Z} \langle \cos^2(m \theta) \rangle, \] (E52)
\[ 1 = J_n \tilde{Z} \langle \cos^2(n(0' - \tilde{\theta})) \rangle. \] (E53)

By changing the variable from \( \theta \) to \( \theta' \), the SPEs can be expressed as
\[ 1 = J_m \frac{1}{\pi} \int_0^{\pi/2} d\psi \int_0^{2\pi} d\theta' g(\omega_0 + A_{\theta + \delta_n} \sin \psi) \times \cos^2 \psi \cos^2(m \theta'), \] (E54)
\[ 1 = J_n \frac{1}{\pi} \int_0^{\pi/2} d\psi \int_0^{2\pi} d\theta' g(\omega_0 + A_{\theta + \delta_n} \sin \psi) \times \cos^2 \psi \cos^2(n(\theta' - \tilde{\theta})). \] (E55)

where \( A_{\theta + \delta_n} = \sqrt{[J_m R_m \cos(m \theta')]^2 + [J_n R_n \cos(n(\theta' - \tilde{\theta}))]^2} \).

Setting \( \tilde{\delta}_n = \alpha_0 - \Theta_{ms} \), we have
\[ A_\theta \cos \tilde{\delta}_n = J_m R_m \cos(\Theta_{nc} - \Theta_{ms}) \cos(m \theta'), \] (E56)
\[ A_\theta \sin \tilde{\delta}_n = J_n R_n \sin(\Theta_{nc} - \Theta_{ms}) \cos(n(\theta' - \tilde{\theta})). \] (E57)

Thus,
\[ \phi_\theta^* = \omega_0 \delta + \sin^{-1} \left( \frac{\omega_0 - \omega_0}{A_\theta} \right) + \tilde{\delta}_n + \Theta_{ms}. \] (E58)

This formula shows that the rotation number can take on values of 0, ±1, ..., ±m.
